When we were converting the SQL file from PostgreSQL to sqlite.   The first thing we have encountered was that we could not put the line where it creates the schema in the beginning of the file. Then we had to change all the types to be valid sqlite. Lastly we had a problem where we could not create a general domain like we did in PostgreSQL. We also had to delete the option cascade whenever we create tables.   In the PostgreSQL file, we created our own type and used the type "enum", however those were invalid in sqlite.
